

Henry Kaiser, Hoover Dam

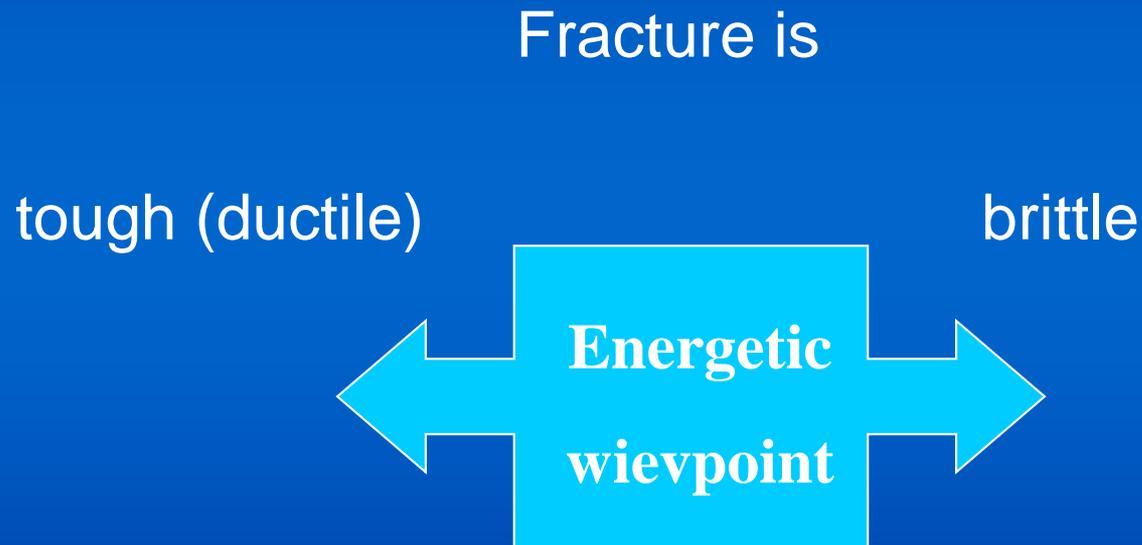

Materials for hydroapplications

Henry Kaiser

- i. Basic notations (transition fracture behaviour of steels, temperature dependence of strength properties, fractography and failure analysis – basic approach)
- ii. (Empirical) tests of toughness/crack resistance (Charpy, Pellini diagram, NDTT)
- iii. Linear – elastic fracture mechanics – LEFM (Irwin, fracture toughness tests), Elastic – plastic fracture mechanics EPFM (tests, interpretation)

**Resistance of the material against fracture
= toughness (ductility)**

Metallic materials with fcc lattice temperature is not deciding

- **Pure metals – plastic deformation preceding to fracture – fracture is ductile**
- **Alloys – dislocation blocking – fracture will be brittle**

Metallic materials with hcp lattice temperature is deciding for the fracture

- **Low number of glide systems – fracture usually brittle**
- **Only at higher temperatures the plastic deformation is possible.**

Metallic materials with bcc lattice

α - iron

temperature, loading rate and stress state are deciding about the type of the fracture

At higher temperatures – fracture usually ductile, at lower temperatures fracture usually brittle

Change of the fracture morphology due to change of the temperature decrease – **transition behaviour of steels**

Temperature of transition is **transition temperature**

At accident – fracture surface inspection - FRACTOGRAPHY

Fracture mechanism – type of fracture (physical, not energetic aspects):

Plastic deformation preceding to fracture (void formation and coalescence) – ductile (microvoid) fracture

Fracture without plastic deformation, propagation along grain boundaries and/or along crystallographic planes – cleavage fracture

**Resistance of the material against fracture
= toughness (ductility)**

Fracture is

tough (ductile)

brittle

- Low energy
- Tough

- Brittle

Intergranular
Transcrystalline

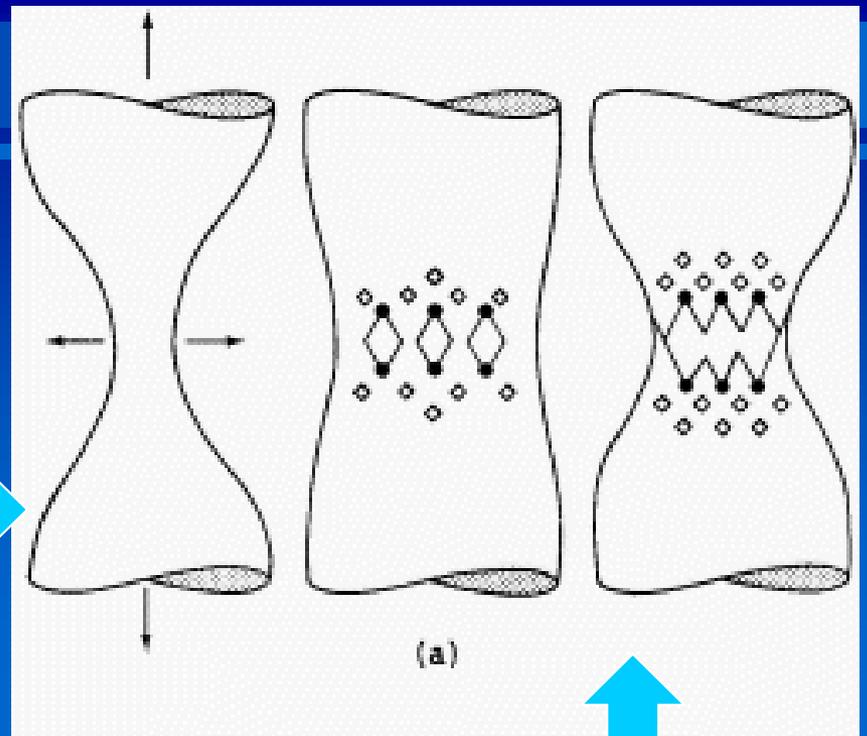

ductile

cleavage

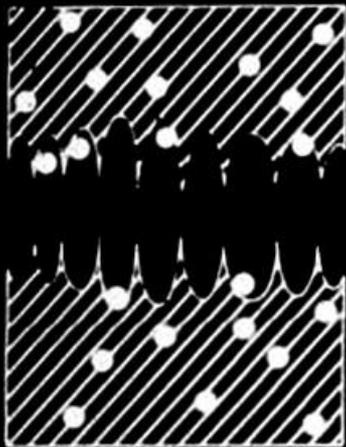

Ductile fracture

0041 20KV X2,000 10µm WD24

Factors deciding about change of the fracture morphology

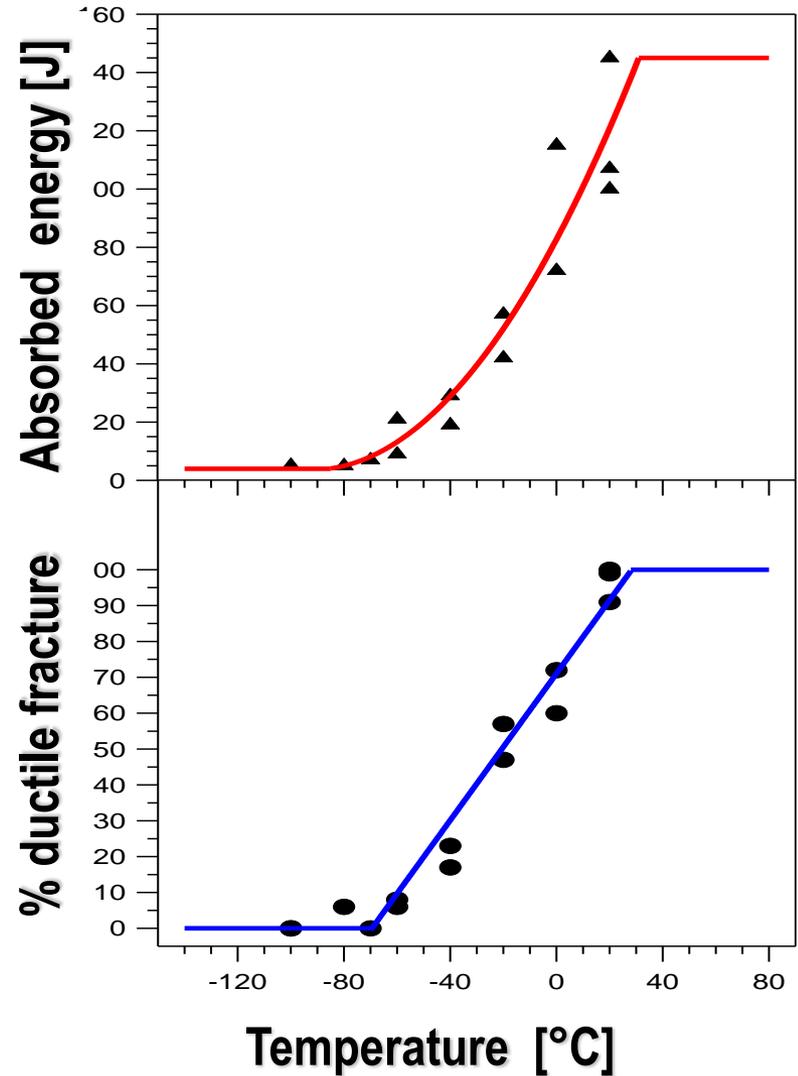

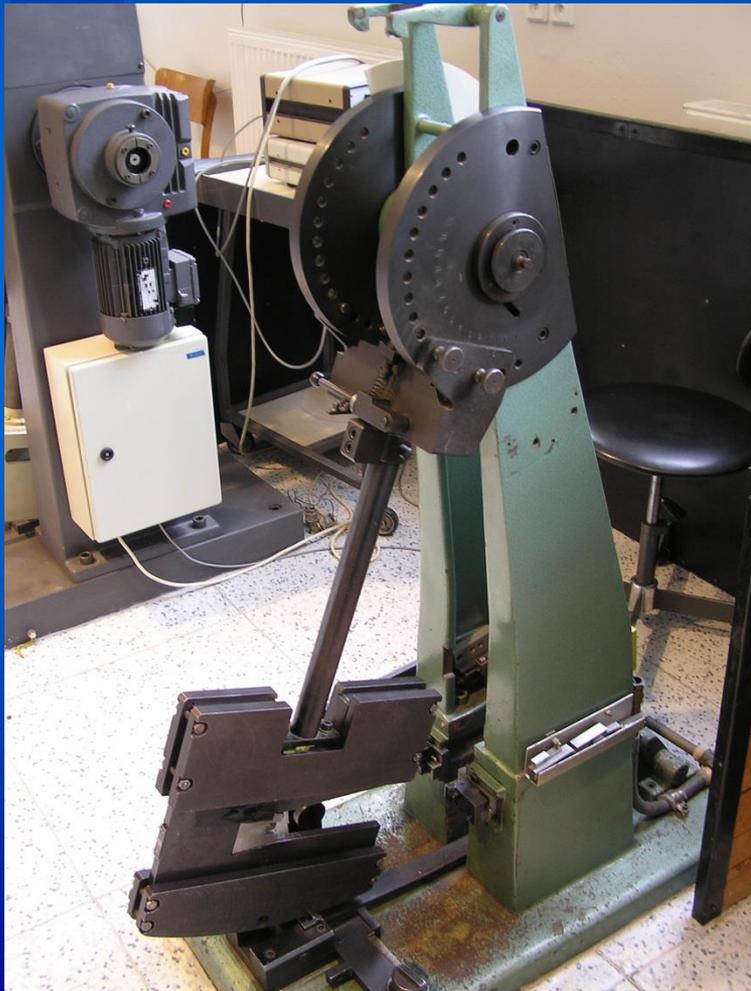

- **External factors**

- Loading conditions: temperature, loading rate, component geometry (stress state, notches presence)

- **Internal factors**

- Steel microstructure (chemical composition, grain size, effect of other microstructural constituents)

Transition fracture behaviour – change of the fracture morphology, micromechanism, impact energy

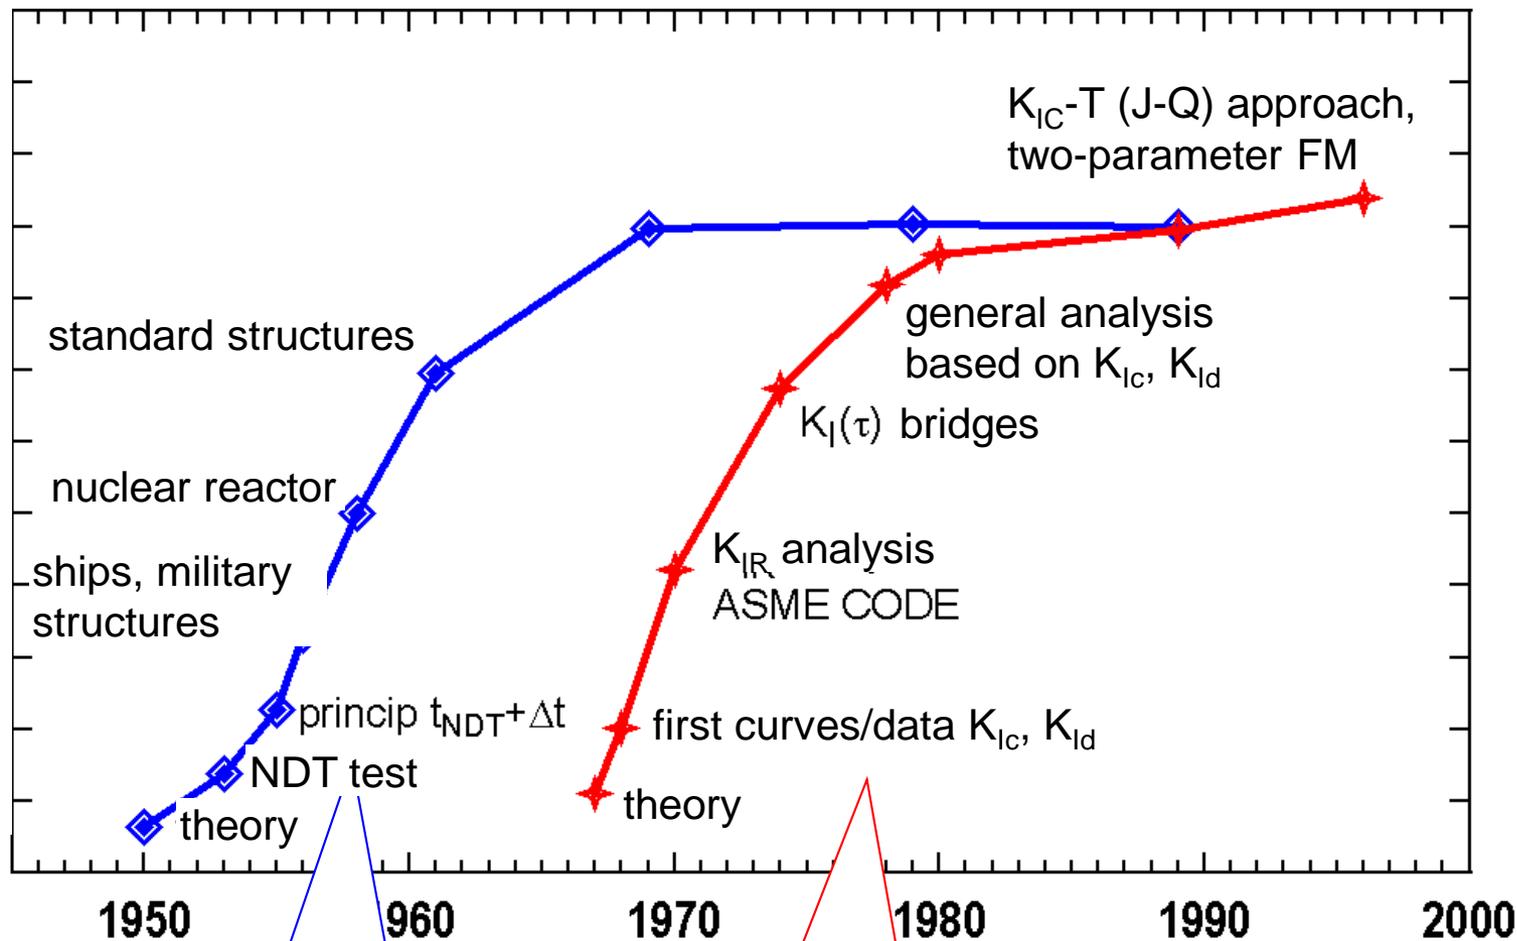

Transition fracture behaviour – change of the fracture morphology, micromechanism, impact energy

How to avoid catastrophic fracture of the component

- crack arrest philosophy - concept of transition temperature
- crack initiation prevention - fracture mechanics concept

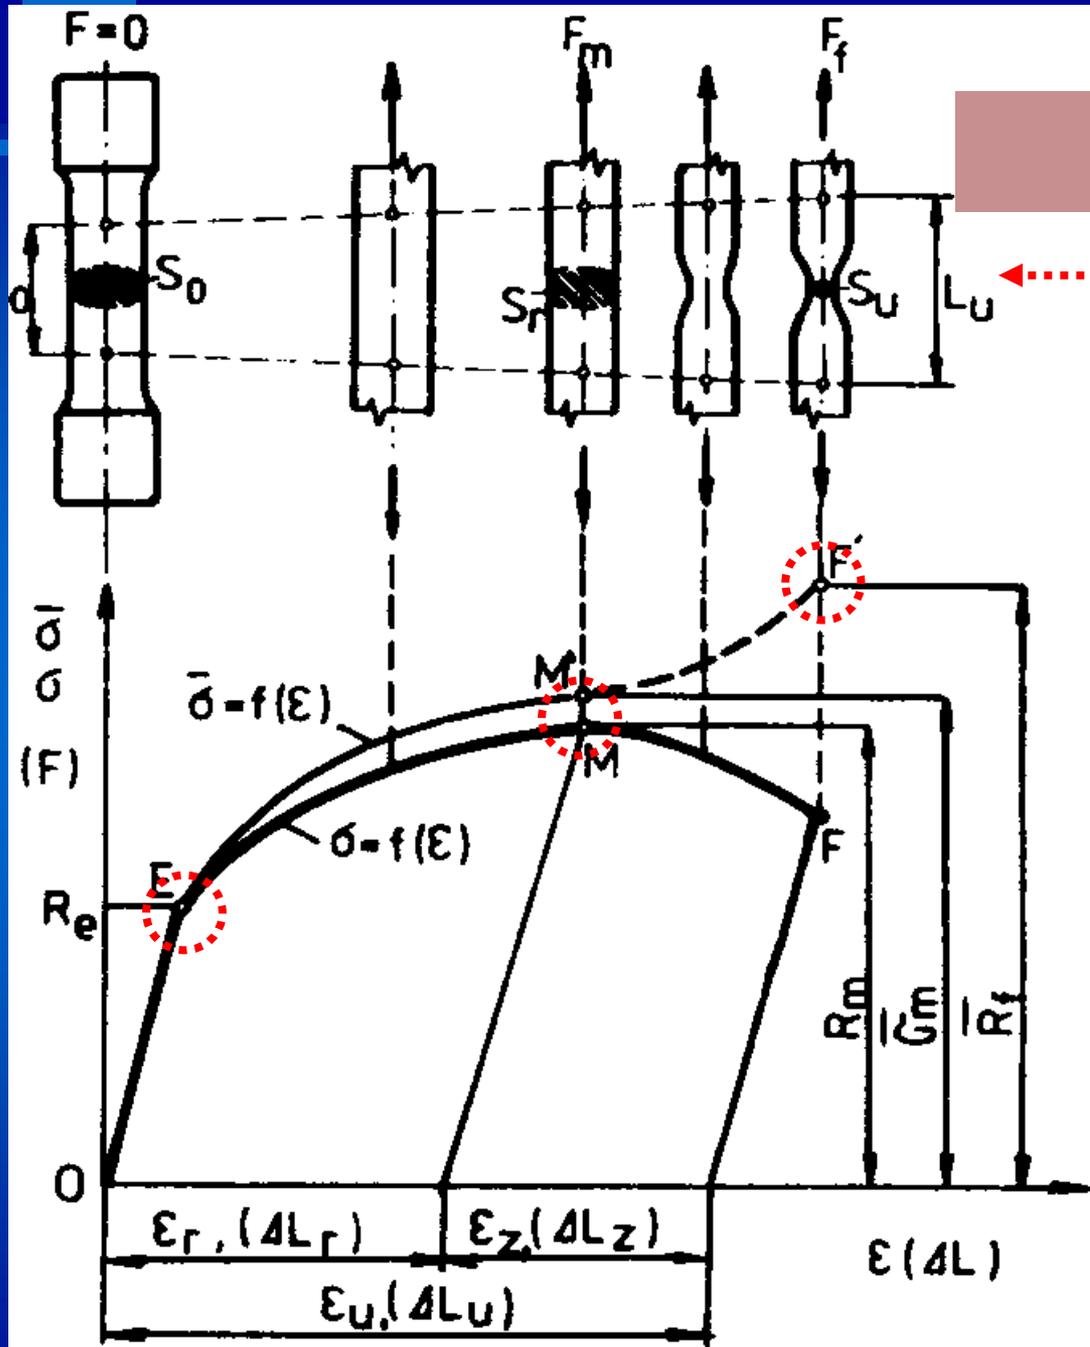

Technological progress

Crack arrest concept

Crack initiation prevention

Transition behaviour

low carbon steel

change of tensile
diagram in temperature
range from 20°C to
269°C

Cleavage fracture stress

Transition behaviour

t_B – brittleness transition temp.
 t_D – ductility transition temp.

- A. Ductile fracture
- B. Mixture duct. x cleav.
- C. Cleavage fracture
- D. Cleavage fracture
- E. Cleavage fracture
- F. Cleavage fracture

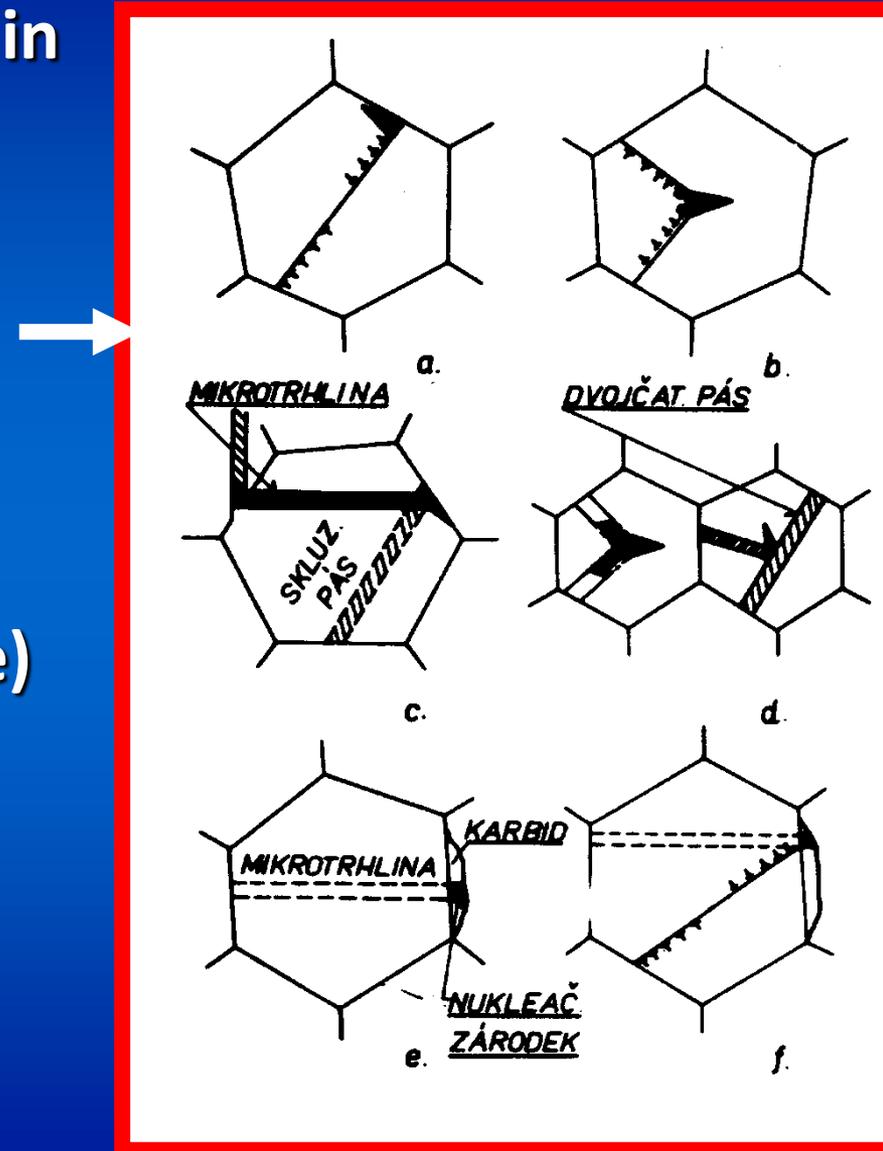

Cleavage fracture stress

Cleavage fracture doesn't occur in under elastic deformations – in any case plastic deformation precedes to cleavage fracture

- lower/upper yield stress, twinning
- intersection of slip bands, slip band to grain boundary (carbide)

The first condition for cleavage fracture:

plastic deformation - it is the necessary condition but not the sufficient one

$$\sigma_{CF}(g) = R_e = \frac{2Gv \cdot \gamma_m}{k_y} d^{-1/2}$$

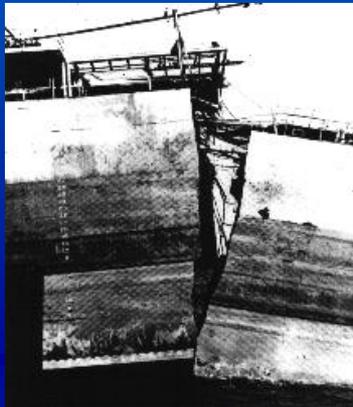

$$v = \frac{2\tau_{\max}}{\sigma_1}$$

In order to increase for the cleavage nucleus tensile stress is necessary (it is the cleavage fracture stress)

Second condition for cleavage fracture: and/or cleavage nucleus propagation
critical (cleavage) fracture stress reaching

- ☞ cleavage fracture stress is lower than theoretical (cohesive) strength
- ☞ value of σ_{CF} depends on steel microstructure
- ☞ fracture nucleation and propagation controlled

Liberty ships have broken at temperatures close to room temperature (not at liquid nitrogen temp.)

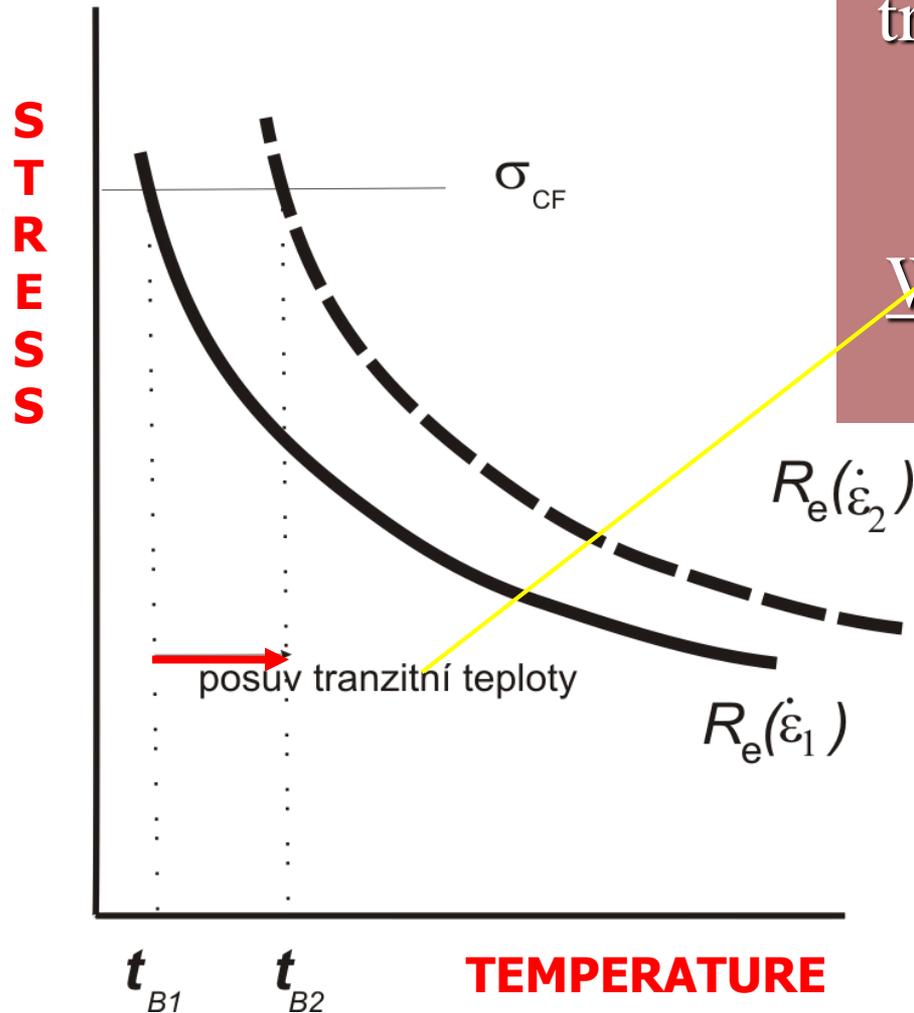

WHY ?

the tensile stress increase on the value of cleavage fracture stress - increased due to

- loading rate increase
- stress concentration effects of notches

Loading rate effect

Higher loading rate moves transition temperatures to higher temperatures !

With increasing loading rate the steel becomes brittler

notch effect / stress concentrators effect

notches presence → stress field

Theoretical stress concentrator $k_t = \alpha$

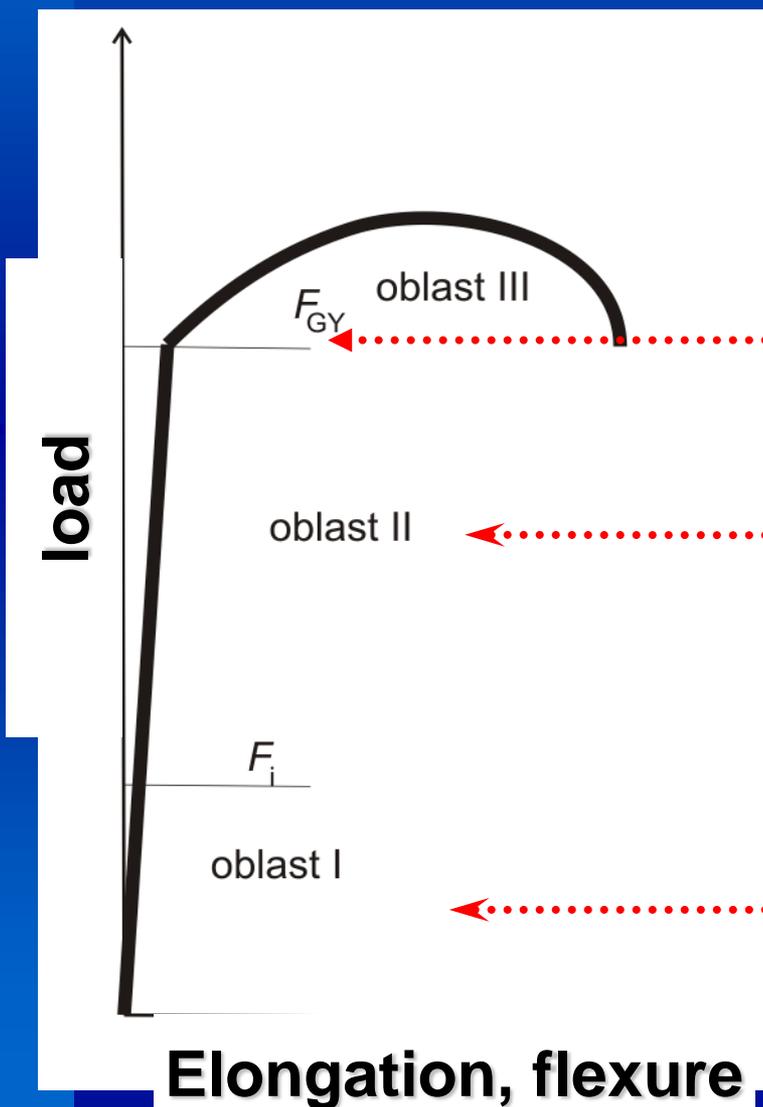

represents localisation of the stress at notch root at elastic deformation

$$k_t = \frac{(\sigma_{yy})^{\max}}{\sigma_n}$$

Plastic stress concentrator represents stress localisation at notch root at local plastic deformation

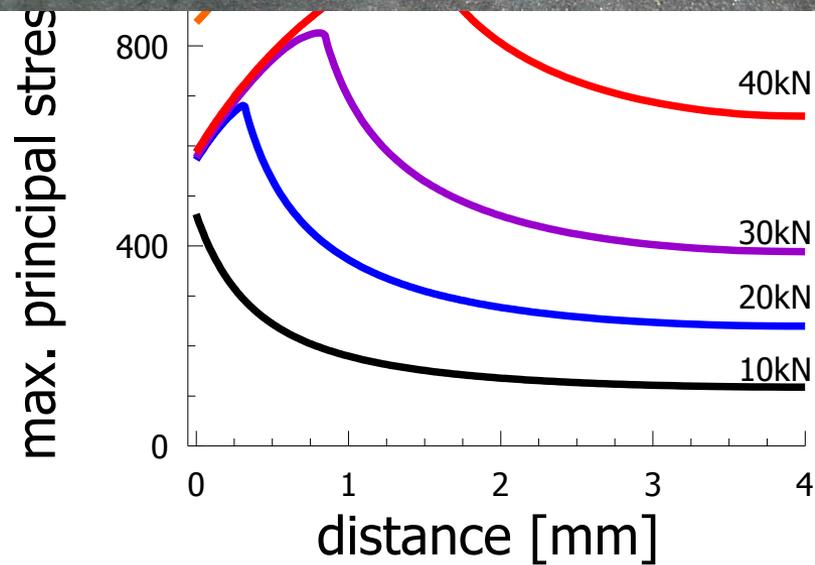

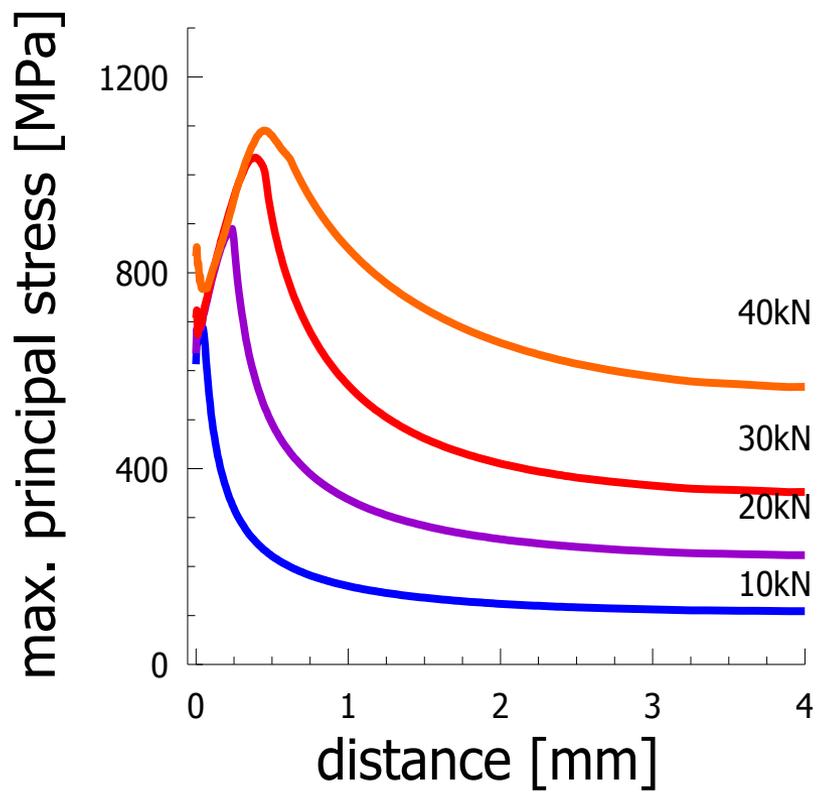

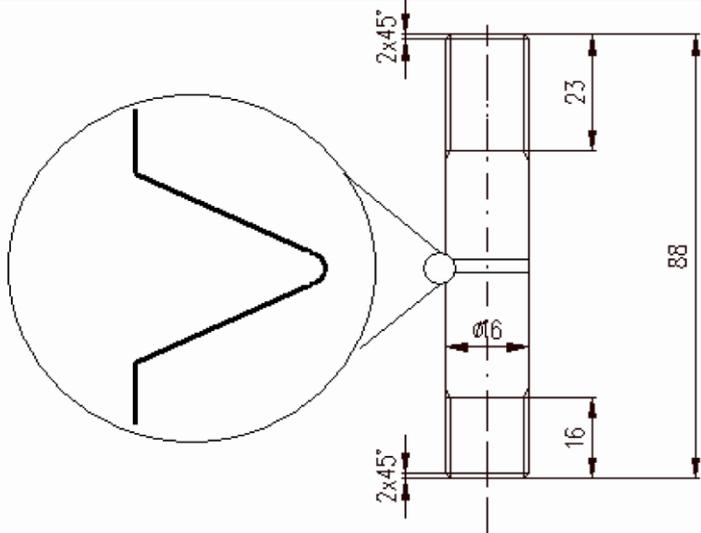

$$k_{\sigma_{pl}} = \frac{\sigma_{yy}}{R_e}$$

Notched sample loading

$$k_{\sigma pl}^{max} = \frac{(\sigma_{yy})^{max}}{R_e}$$
$$k_{\sigma pl} = \frac{\sigma_{yy}}{R_e}$$

$$k_t = \frac{(\sigma_{yy})^{max}}{\sigma_n}$$

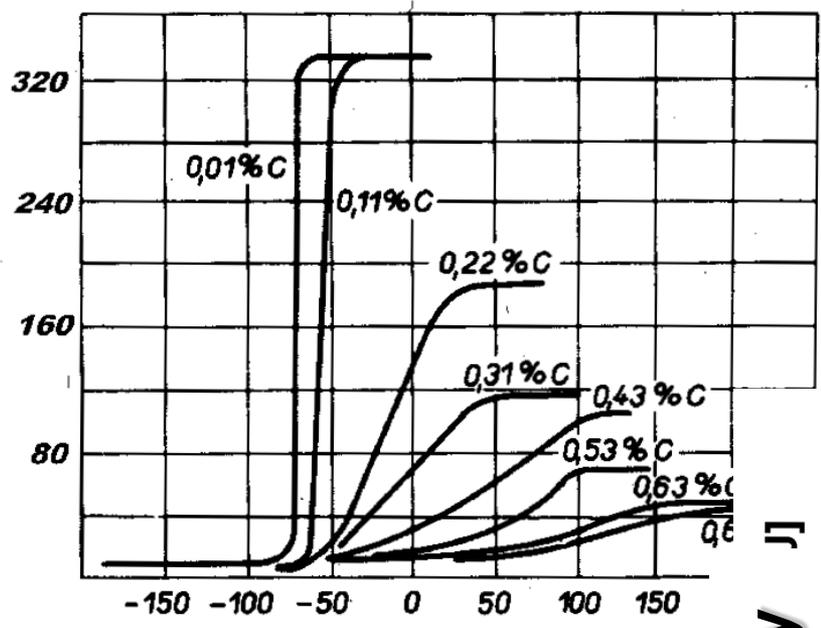

Cleavage fracture stress

cleavage fracture stress controls crack resistance of the steel against brittle fracture not only at uniaxial loading but also in triaxial stress state (samples/components with notches)

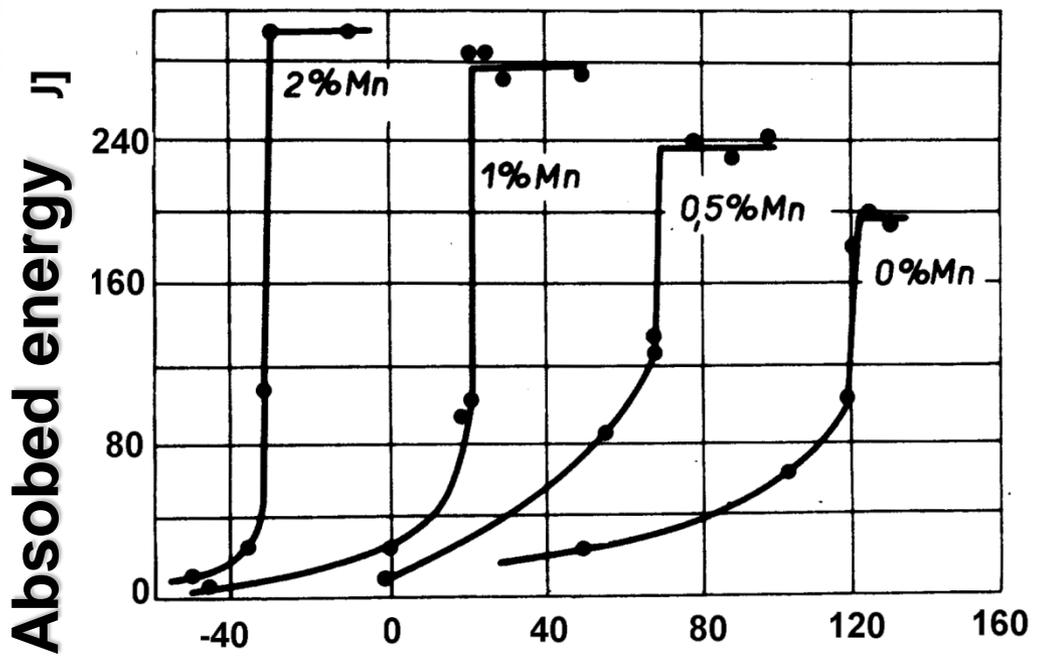

there is a small plastically deformed region, in which tensile stress is acting which higher/the same as cleavage fracture stress σ_{CF} .

Absorbed energy

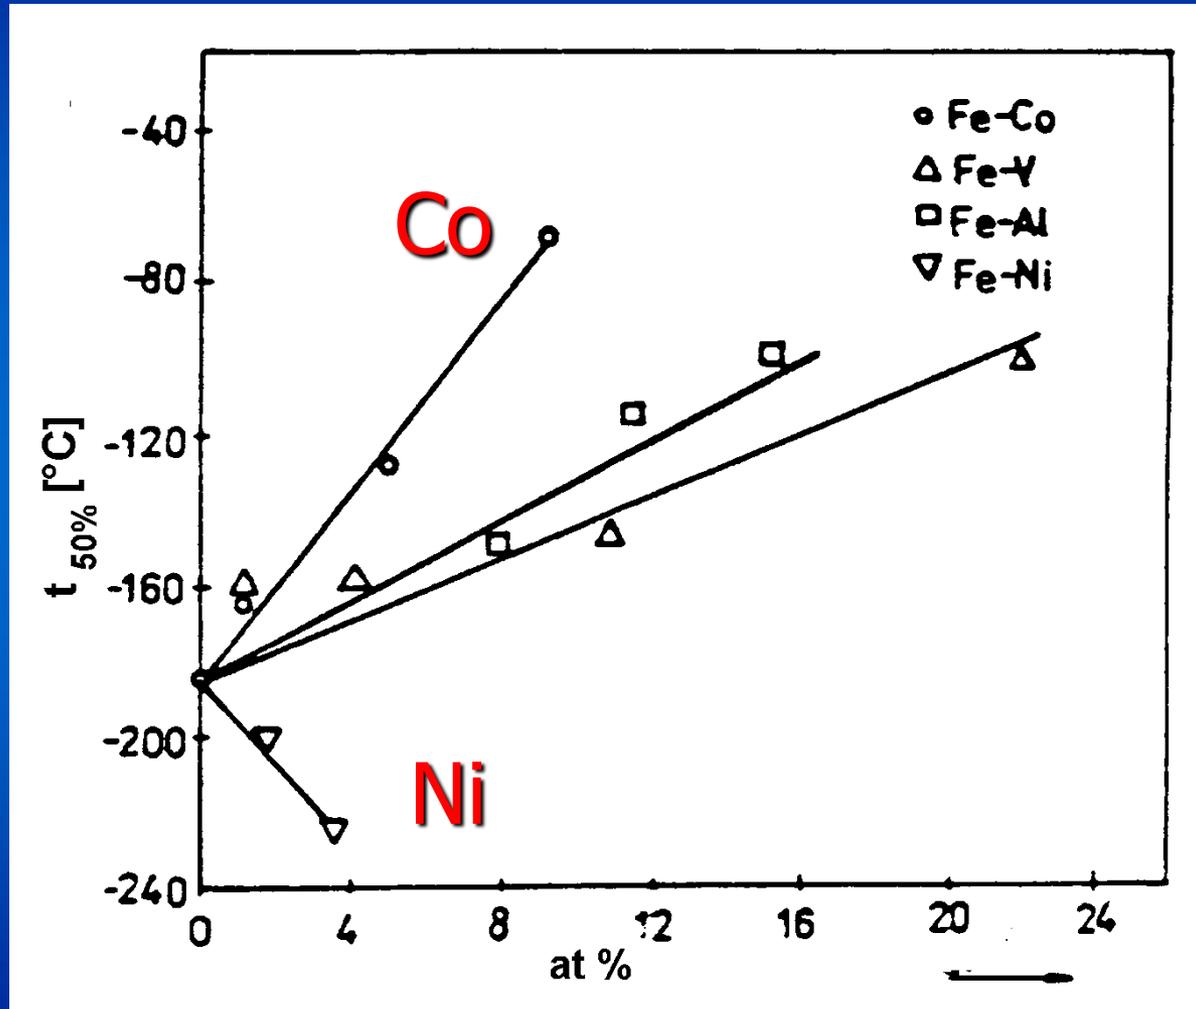

temperature

Effect of microstructure on transition behaviour

temperature

Effect of alloying elements on transition behaviour

Low alloy steels for lower temperatures

- temperatures – 50°C up to – 150°C
- alloying elements 1,5% Ni, 0,15% Cr, 0,1% Mo

Highly alloyed steels for cryogenic temperatures

- -150°C up to -196°C
- Low alloy martensite
(0,04 až 0,14) %C, (5 až 13) % Ni
- Steels of the type
COR 13/4; 13/6 (Cr/Ni)
